The software, which is now available in beta version 2.4, now comes with an easy-to-use system that allows users to log in with fingerprints. It is a part of the software package that focuses on secure remote system access and is part of a unified system called Blabla in which the user's prints are scanned and sent to a remote server where the user is authenticated. The purpose is to provide more opportunities for secure remote access than a password or a key. One way to achieve this is to embed the fingerprint data into the system's objects, such as a file, a component, or a tool. "Currently, in IT environments, for remote access to computers, we use passwords and keys, which are stored on an object, such as a computer, server, tablet, or cell phone, and are either generated or entered by users," says Marc Renne, CTO at griaula. "That's fine in a relatively secure environment, but there are many cases where passwords or keys are forgotten, or they are used for multiple devices. This is where our technology can make the difference, and make the tasks we do more secure." In the event of a network outage, the user's data, including passwords and access keys, will remain safe. Another advantage is that users can log in by scanning their fingerprints with one single interface. This eliminates the need for two key combinations: a fingerprint and a password. The software includes two main components: fingerprint scanning hardware and the fingerprint recognition software. The hardware is comprised of a sensor, a reader, and a security adapter. The software is known as griaula. In the first implementation of the software, the user's fingers are captured with a passive sensor and a reader on a small plastic badge. This sensor produces a 2D fingerprint image that is converted to a real-time encoding (RTC) format in griaula. The RTC encoding is then transmitted via Bluetooth to the computer or mobile device on which the software is installed. The software supports the conversion of fingerprints to both ECC (enhanced curve coding) and NTRU formats, the latter of which is a proprietary format of NTRU encryption technology, which is open to public review. The griaula software was developed by Renne and his team, including CTO Marc Renne, CTO Olivier Roger, CTO/CTO& Developer Peter Nilsson, and Software Developer Henri Schuen f3e1b3768c
