CheckFolder is a free tool that enables Windows users to check whether files are corrupted on optical or external drives or if entire drives are damaged. Starting with Windows XP, manufacturers could print their own manufacturer codes on the back of display devices to help users identify their latest equipment. But without working codes, tech-savvy consumers would have to disassemble the driver, read the date and time manually, and then find the equivalent numerical code using other information on the drive. Microsoft has worked to simplify the process of identifying faulty hardware by releasing Windows Device Manager and its new

support for manufacturer code printing. The first of its kind in Windows, Device Manager can display the code to the user of any device, even if they do not have the original codes. If you've installed firmware updates from your PC manufacturer and then tried to reinstall or recover lost data, you may have noticed that a lot of the data are missing from the recovery drive or the original operating system. This is because Windows can sometimes cause damage to the data on the drive during the recovery process. Such a problem can be minimized by using a flash-based Data Recovery software. But if you have a damaged OS, you can try using a recovery or startup disk to repair any OS-related damage that may have occurred. A startup or recovery disk

can repair a damaged operating system by the use of a series of bootable installation media: USB flash drive, CD, or DVD. It is created as a system diagnostic tool to check, test, repair, restore and reinstall the operating system or the affected hardware. A startup or recovery disk keeps the system boot sequence on the disk, and as it is a bootable media, you can use it to boot the operating system and then repair the damaged OS. Startup/recovery disk is a CD, DVD, USB stick, a hard drive, or a network drive containing the operating system and its data, as well as the drivers for your hardware. It starts the system in read-only mode and can repair the following: The lack of a compatible driver for your hardware. Problem with the

computer system itself. Inability to start the system or the computer due to the inability of the hardware to be detected. Data loss caused by virus, power outage, or hardware failure. Data lost in a corrupted system file NTFS volume corruption due to hardware failure or a virus. Windows

Additional Notes: Up to two separate macros can be loaded simultaneously, each with its own functionality. This is a highly recommended if you want to streamline your work on a large amount of assets. However, some may experience performance hit with two different macros running at the same time. This might also be the case if you're using multiple machines to accomplish a single task. Possible to use the native Visual Studio Macros plugin too. Either the web version of it or the VS11. Python 3.7 compatible. Macro creation
