Preparing the artwork Preparing an artwork for printing usually consists of two steps: \* First, you need to \_convert\_ a grayscale or RGB image (or use a print-specific color mode) to the correct color mode and resolution. Then you need to \_resize\_ the image for a specific size on your output device. In Chapter 10, we show you how to convert an image from RGB to CMYK, and what resolution to choose.

Fuel cells have received much attention in recent years as the next generation of energy technology. One type of fuel cell is a solid oxide fuel cell (SOFC). This type of fuel cell is similar to traditional fuel cells in that it generates electricity through the chemical reaction of oxygen and a reducing agent, such as hydrogen or a hydrogen-containing gas. Thus, a SOFC requires fuel to be processed into a hydrogen-containing gas prior to entering the fuel cell. In the typical SOFC, such fuel processing requires significant quantities of relatively expensive hydrogen gas and complex control systems. Therefore, it is desirable to eliminate the need for hydrogen processing and to provide a compact SOFC system that requires fewer components and less space. Hence, what is needed is a fuel cell that does not require hydrogen processing prior to entering the fuel cell. What is also needed is a fuel cell that is compact and efficient.

1. Field of the Invention The present invention generally relates to a semiconductor package technology, and more particularly to a method of fabricating a laminated chip package.
2. Description of Related Art Semiconductor chip packaging technology refers to a technology in which a semiconductor chip is provided with an encapsulant package, and the encapsulant package is electrically connected to an external printed circuit board (PCB). A conventional semiconductor package technology known as a wafer level chip scale package (WLCSF) is characterized in that since a plurality of semiconductor chips is fabricated on a wafer, then the plurality of chips is encapsulated at the wafer level. The conventional semiconductor package technology is also characterized in that after the plurality of chips is encapsulated, the wafer and other elements are ground and polished to achieve a thickness adjustment and a planarization. As such, the conventional semiconductor package technology has a shorter process cycle and an increased packaging density. When the semiconductor package technology is developed, electrical bonding and thermal curing must be considered. When the chip scale package is about 20  $\mu\text{m}$  to about 30  $\mu\text{m}$ , the semiconductor chip is electrically bonded to a printed circuit board (PCB) or to another chip using a conductive adhesive. Then, a thermal curing process is performed in order to cure the conductive adhesive. The cured conductive adhesive is encapsulated in a molding package. Conventionally, the thermal curing process is performed to cure the conductive adhesive in a molding package that has an encapsulant. When forming the package, the thermal curing is
